

# High-voltage switchgear early warning busbar

## Overview

---

Non-contact infrared sensors continuously monitor busbar temperature from a safe distance within cabinets, avoiding physical contact or complex insulation requirements. Electrical failures are caused by a number of different factors, including: Continuous thermal monitoring technology enables critical MV switchgear joints and busbar connections to be monitored in real-time. Thermal monitoring locations include: Eaton Exertherm CTM solution for MV switchgear. Such fluctuations can eventually lead to insulation aging, poor contact, and even major fire. Busbars have typically been left without dedicated protection, from the following reasons: It is a fact that the risk of a short circuit happening on modern metal clad equipment is insignificant, but it cannot be completely dismissed. High-impedance voltage differential protection is a solution to the challenge of CT saturation during external faults, as the high impedance of the relay forces the error current due to the saturated CT back through the CTs instead of the relay operating coil.
